

流畅的Python笔记

Python数据模型

- 数据模型 其实是对 Python 框架的描述,它规范了这门语言自身构建模块的 接口,这些模块包括但不限于序列、迭代器、函数、类和上下文管理器。
- `collections.namedtuple` 用以构建只有少数属性但是没有方法的类

```
import collections
Card = collections.namedtuple('Card', ['rank', 'suit'])
beer_card = Card('7', 'diamonds')
beer_card
```

- `in`

For user-defined classes which define the `__contains__()` method, `x in y` returns `True` if `y.__contains__(x)` returns a true value, and `False` otherwise.

For user-defined classes which do not define `__contains__()` but do define `__iter__()`, `x in y` is `True` if some value `z` with `x == z` is produced while iterating over `y`. If an exception is raised during the iteration, it is as if `in` raised that exception.

Lastly, the old-style iteration protocol is tried: if a class defines `__getitem__()`, `x in y` is `True` if and only if there is a non-negative integer index *i* such that `x == y[i]`, and all lower integer indices do not raise `IndexError` exception. (If any other exception is raised, it is as if `in` raised that exception).

- `a + b`

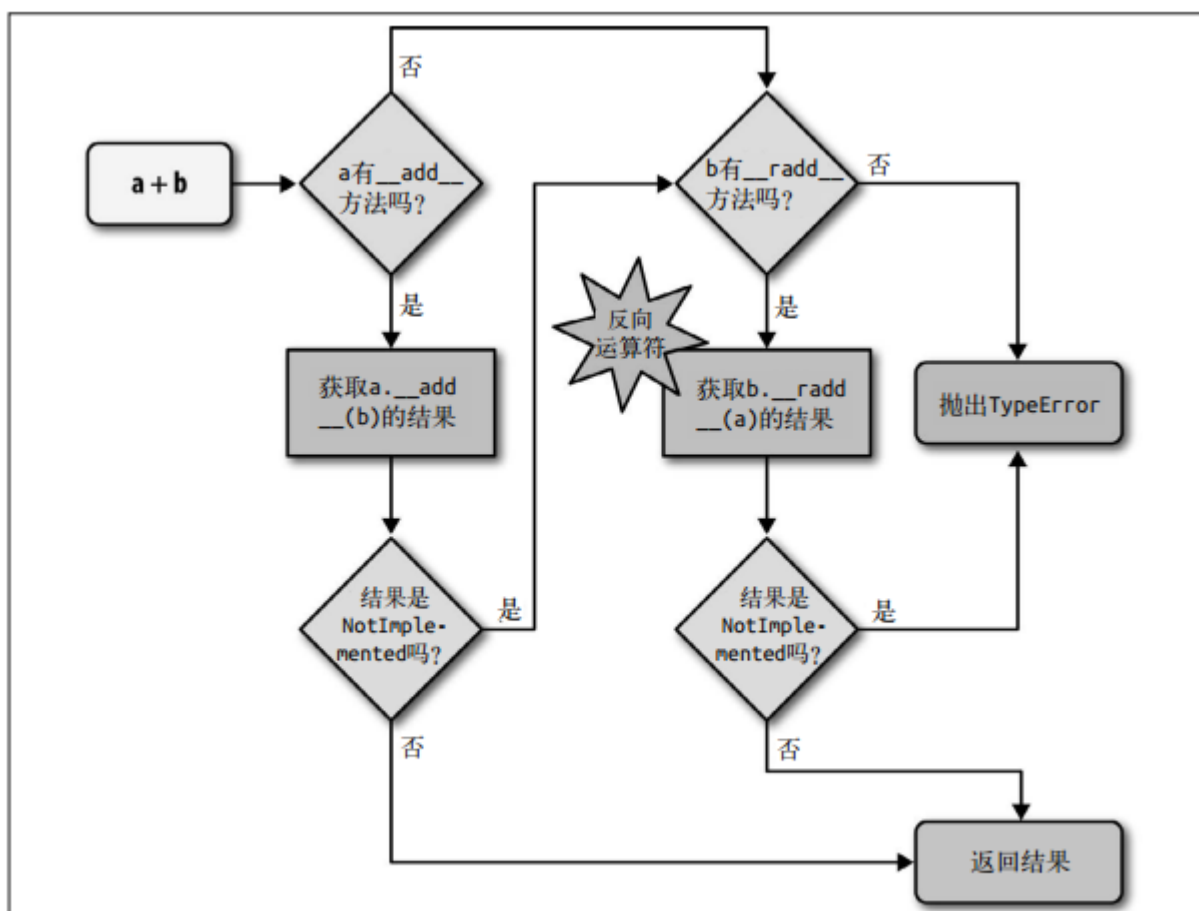

图 13-1: 使用 `__add__` 和 `__radd__` 计算 `a + b` 的流程图

命名空间与作用域

A *scope* is a textual region of a Python program where a namespace is directly accessible.

命名空间

- Local (局部命名空间)
- Global (全局命名空间)
- Built-in (内建命名空间)

作用域

- Local (函数内部) 局部作用域
- Enclosing (嵌套函数的外层函数内部) 嵌套作用域 (闭包)
- Global (模块全局) 全局作用域
- Built-in (内建) 内建作用域

```
# test.py
def test():
    print(__file__)
    __file__ = 'test'
    print(__file__)

print(__file__)
__file__ = 'test1'
print(__file__)

test()
```

```
>>> python test.py
test.py
test1
Traceback (most recent call last):
  File "test.py", line 12, in <module>
    test()
  File "test.py", line 2, in test
    print(__file__)
UnboundLocalError: local variable '__file__' referenced before assignment
```

序列构成的数组

内置序列类型

- 容器序列: 能存放不同类型的数据

`list` `tuple` `collections.deque`

- 扁平序列: 只能容纳一种类型

`str` `bytes` `bytearray` `memoryview` `array.array`

容器序列存放的是它们所包含的任意类型的对象的引用,而扁平序列里存放的是值而不是引用。

- 可变序列

`list` `bytearray` `array.array` `collections.deque` `memoryview`

- 不可变序列

`tuple` `str` `bytes`

列表推导和生成器表达式

- 列表推导不会再有变量泄漏的问题

```
Python 2.7.6 (default, Mar 22 2014, 22:59:38)
[GCC 4.8.2] on linux2
Type "help", "copyright", "credits" or "license" for more information.
>>> x = 'my precious'
>>> dummy = [x for x in 'ABC']
>>> x
'C'
```

```
>>> x = 'ABC'
>>> dummy = [ord(x) for x in x]
>>> x
'ABC'
>>> dummy
[65, 66, 67]
>>>
```

- 生成器表达式

生成器表达式背后遵守了迭代器协议,可以逐个地产出元素,而不是先建立一个完整的列表,然后再把这个列表传递到某个构造函数里。

生成器表达式的语法跟列表推导差不多,只不过把方括号换成圆括号而已。

```
>>> colors = ['black', 'white']
>>> sizes = ['S', 'M', 'L']
>>> for tshirt in ('%s %s' % (c, s) for c in colors for s in sizes):
...     print(tshirt)
...
black S
black M
black L
white S
white M
white L
```

元组

- 不可变列表
- 没有字段名的记录
 - `*` 运算符把一个可迭代对象拆开作为函数的参数

```
>>> def test(a, b, c, d):
...     print(a, b, c, d)
...
>>> test(1, *range(2), 3)
1 0 1 3
```

- 用 `*` 来处理剩下的元素

```
>>> a, *body, c, d = range(5)
>>> a, body, c, d
(0, [1, 2], 3, 4)
>>> *head, b, c, d = range(5)
>>> head, b, c, d
([0, 1], 2, 3, 4)
```

- `collections.namedtuple`

The `collections.namedtuple` function is a factory that produces subclasses of `tuple` enhanced with field names and a class name

```
>>> from collections import namedtuple
>>> City = namedtuple('City', 'name country population coordinates')
>>> tokyo = City('Tokyo', 'JP', 36.933, (35.689722, 139.691667))
>>> tokyo
City(name='Tokyo', country='JP', population=36.933, coordinates=(35.689722,
139.691667))
>>> tokyo.population
36.933
>>> tokyo.coordinates
(35.689722, 139.691667)
>>> tokyo[1]
'JP'
```

切片

`a:b:c` 这种用法只能作为索引或者下标用在 `[]` 中来返回一个切片对象: `slice(a, b, c)`

对 `seq[start:stop:step]` 进行求值的时候,Python 会调用 `seq.__getitem__(slice(start, stop, step))`
